

# In-House Medical Treatments for a New Health Care System

- When at home and receiving an in-house medical treatment, there are times when you unintentionally neglect or forget treatment.
- There is no way to find out when it will happen, so this could make your family, or yourself worried.
- To go to the hospital just for something small could be a burden for time and for cost on the patient.

With this system, for patients or the elderly receiving in-house treatments while living by themselves can use IPv6 to connect to a hospital, manage their treatments, and can ask for help at any time.

The hospital can check on the patient when they check blood pressures and weights, with a sensor on a pill case, the hospital can check if the patient forgot about taking the medicine.

On a cellular phone, there could be a function where the patient could call a nurse, and when they leave the house for whatever reason, they could get held with a push of a button. When they require help from an ambulance, they could quickly gather information about the patient from the hospital that they are being treated at.

Through a television screen, they could get direct information about their treatment from a doctor in that field, and if they ask a question or want their current health status from the hospital the patient could get a reply back within 24 hours.

There could be a recipe on what sort of meal the patient should eat, and also by reporting what the patient ate during the day the hospital could warn them if there was something they should not have ate.
